

*Cognitive Vitality Reports® are reports written by neuroscientists at the Alzheimer's Drug Discovery Foundation (ADDF). These scientific reports include analysis of drugs, drugs-in-development, drug targets, supplements, nutraceuticals, food/drink, non-pharmacologic interventions, and risk factors. Neuroscientists evaluate the potential benefit (or harm) for brain health, as well as for age-related health concerns that can affect brain health (e.g., cardiovascular diseases, cancers, diabetes/metabolic syndrome). In addition, these reports include evaluation of safety data, from clinical trials if available, and from preclinical models.*

## Vitamin K<sub>2</sub>

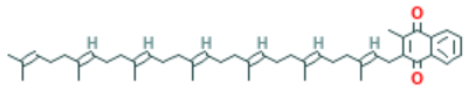

### Evidence Summary

Some evidence suggests that vitamin K<sub>2</sub> may be beneficial for cardiovascular disease, cancer, and osteoporosis.

**Neuroprotective Benefit:** There is little evidence that supplementation with vitamin K<sub>2</sub> will benefit brain health, unless, perhaps, there is a vitamin K<sub>2</sub> deficiency.

**Aging and related health concerns:** Some epidemiological evidence suggests that high intake of vitamin K<sub>2</sub> may improve cardiovascular or metabolic outcomes, though the evidence for supplementation is mixed (except possibly for cancer or osteoporosis).

**Safety:** Vitamin K<sub>2</sub>, in doses used in clinical trials, appears relatively safe for long-term use.

<p><b>Availability:</b> Available as a supplement (look for fermented forms of MK-7, preferably supplements that contain MenaQ7, e.g. <a href="#">link</a>)</p>	<p><b>Dose:</b> 100µg/day to 360µg/day</p>	<p><b>Molecular Formula:</b> C<sub>46</sub>H<sub>64</sub>O<sub>2</sub></p> <p><b>Molecular weight:</b> 649g/mol</p>  <p>MK7</p> <p>Source: <a href="#">Pubchem</a></p>
<p><b>Half-life:</b> MK-7 ~ 70 hours</p>	<p><b>BBB:</b> MK-4 Penetrant in animals</p>	
<p><b>Clinical trials:</b> 28 completed, 16 ongoing (most studies &lt;100 participants for MK-7; osteoporosis studies ~9,000 participants for vitamin K<sub>2</sub>)</p>	<p><b>Observational studies:</b> 11 completed (most dietary intake studies between 3,000-30,000 individuals).</p>	

### What is it?

Vitamin K represents several molecules including the phyloquinone (vitamin K<sub>1</sub>) and the menaquinones (vitamin K<sub>2</sub>). They play a role in coagulation (in fact, one class of anti-coagulants is vitamin K antagonists, such as warfarin). They are also thought to play a role in improving bone health, reducing vascular calcification, and reducing cardiovascular risk. Vitamin K<sub>1</sub> and K<sub>2</sub> act by interacting with vitamin K-dependent proteins (VKPDs) including those involved in the coagulation cascade (such as Factors II, VII, IX, X) and proteins involved in bone and soft-tissue mineralization (such as osteocalcin and Matrix Gla protein, respectively) ([El Asmar et al, 2014](#)).

Dietary vitamin K<sub>1</sub> is more common and comes primarily from green vegetables such as spinach, broccoli, kale, and Brussels sprouts. Dietary vitamin K<sub>2</sub> is of microbial origin and often comes from cheese, yogurt, and natto (fermented soybeans). Since dietary vitamin K<sub>1</sub> is more prevalent, the USDA recommendations for vitamin K intake refer to vitamin K<sub>1</sub>. However, it is estimated that 10%-25% of vitamin K consumption is vitamin K<sub>2</sub>. There is growing evidence that vitamin K<sub>1</sub> and K<sub>2</sub> play slightly different roles in the human body. There is currently no Recommended Dietary Intake (RDI) value for vitamin K<sub>2</sub>, though calls have been made to make one ([Akbulut et al, 2020](#)).

There are several form of vitamin K<sub>2</sub>, the most relevant to human health being menaquinone-4 (MK-4) and menaquinone-7 (MK-7). MK-4 is the most common dietary source of vitamin K<sub>2</sub> and is produced by the conversion in tissue and/or bacteria of vitamin K<sub>1</sub>. It is water soluble and can be obtained from the consumption of animal products. Longer-chained menaquinones such as MK-7 (also MK-8 and MK-9) are primarily found in fermented foods, such as natto or hard cheese ([Akbulut et al, 2020](#)).

K vitamins are characterized by a quinone ring but have different chain lengths and degrees of saturation. The naming of the menaquinones is MK-n, where n is the number of isoprenoid side chain residues (e.g., MK-4 is a quinone ring with four isoprenoid side chains) ([Beulens et al, 2013](#)).

#### *Trans* MK-7

Long chain menaquinones, such as MK-7, can exist in several geometric isomers, *cis*, *trans*, and *cis/trans*. The *trans* isomer of MK-7 has the greatest biological activity (the *cis* form is estimated to have 1% of the biological activity of *trans*). *Trans* MK-7 exists in a linear formation while *cis* MK-7 is non-linear. The *cis* conformation impairs its ability to interact with subcellular proteins. Naturally occurring isomers of MK-7 are in the *trans* configuration. However, some commercial preparations may contain both *cis* and *trans* isomers. In addition, autoxidation by exposure to atmospheric oxygen, light, and elevated temperature during storage may also convert *trans* MK-7 to *cis* MK-7 ([Sitkowski et al, 2018](#)).

Commercial supplements of MK-7 can be produced naturally, by fermentation, or through chemical synthesis. MK-7 is produced by fermentation using several bacterial strains, the preferred strain being *Bacillus subtilis natto*. It is assumed that natural synthesis of MK-7 using bacterial fermentation will produce all *trans* MK-7 ([Lal and Berenjian, 2019](#)). The amount of MK-7 in different supplements varies, with soft pills often having greater amounts of MK-7 than reported on the label and hard pills having less. Some commercial supplements claiming MK-7 was created using fermentation methods were reported to contain significant amounts of *cis* MK-7, suggesting that the provider is disingenuous as to their production methods (see paragraph below on chemical synthesis ([Szterk et al, 2018a](#), [Szterk et al, 2018b](#))).

MK-7 can also be produced through chemical synthesis. However, this method will often convert *trans* MK-7 to *cis/trans* MK-7 in ratios of 3:1 or 2:1. Therefore, the use of fermented forms of MK-7 is preferred. The largest supplier of fermented MK-7 is [MenaQ7](#) from Nattopharma. It is not sold directly from Nattopharma to consumers. Rather they sell it to many supplement providers to use in their products ([link](#)).

This report is specific for vitamin K<sub>2</sub>, so only studies that specify vitamin K<sub>2</sub> it will be included in the analysis. Of the individual menaquinones, MK-7 was primarily studied for age-related indications. MK-4 is the most prevalent form of vitamin K<sub>2</sub> in the brain (more than 98%) and was used in neuroprotection studies.

**Neuroprotective benefit:** There is little evidence that supplementation with vitamin K<sub>2</sub> will benefit brain health, unless, perhaps, there is a vitamin K<sub>2</sub> deficiency.

Types of evidence:

- One post-mortem study in humans
- Four preclinical studies

Human research to suggest prevention of dementia, prevention of decline, or improved cognitive function?

Plasma and post-mortem tissue from 48 individuals (98-107 years of age, 25 demented, 23 nondemented) from the Georgia Centenarian study were collected and used to correlate MK-4 levels to cognition measured one year before death. MK-4 was the predominant type of vitamin K in brain tissue. Individuals taking anti-thrombotic drugs had up to 53.9% lower levels of MK-4 in the brain. Cognitive function was not associated with circulating MK-4 levels before or after excluding antithrombotic non-users. The authors suggested that once brain's MK-4 needs are met, higher levels are not necessarily better ([Tanprasertsuk et al, 2019](#))

Human research to suggest benefits to patients with dementia:

None

Mechanisms of action for neuroprotection identified from laboratory and clinical research

Alzheimer's – Preclinical Study

In a rat model of Alzheimer's disease (colchicine-induced memory impairment which decreases activity of acetylcholinesterase – AChE), treatment with a nutraceutical formulation from fermented soybeans (NN – contains nattokinase, daidzin, genistin, glycitin, and MK-7) over 28 days improved memory, reduced hippocampal protein carbonyl content, increased AChE activity, reduced lipid peroxidation levels, and increased antioxidant protein levels (glutathione, superoxide dismutase, and catalase) ([Bhatt et al, 2017](#)).

### *Cognition – Preclinical Studies*

It was reported that MK-4 represents more than 98% of the total levels of vitamin K in the brain of young and old rats, and that MK-4 decreased as a function of age (note – some vitamin K<sub>2</sub>-dependent proteins – anticoagulant proteins C and S, and Gas6 – also have functions in the brain). *In vitro* studies suggest that MK-4 may have neuroprotective, antioxidant, and anti-inflammatory properties ([Ferland, 2013](#)). In a rat model of metabolic syndrome (high fat high fructose), 10-week treatment with vitamin K<sub>2</sub> improved anxiety and depression symptoms but had no effect on memory ([Gancheva et al, 2016](#)).

### *Stroke – Preclinical Studies*

In a rat model of cerebral ischemia/reperfusion, treatment with a high dose of MK-4 (400mg/kg) reduced mortality after 24 hours. After seven days, MK-4 (400mg/kg) improved cognitive function, and reduced brain edema, cell death, neuronal death, gliosis, inflammatory markers (IL-6, IL-1 $\beta$ , TNF $\alpha$ ), and nitrates ([Moghadam and Fereidoni, 2020](#)).

### APOE4 Interactions:

Nothing reported for cognition. One study suggested that ApoE4 does not alter the risk of hip fracture due to low vitamin K<sub>2</sub> intake ([Apalset et al, 2011](#)).

**Aging and related health concerns:** Some epidemiological evidence suggests that high intake of vitamin K<sub>2</sub> may improve cardiovascular or metabolic outcomes, though the evidence for supplementation is mixed (except possibly for cancer or osteoporosis).

### Types of evidence:

- One meta-analysis of vitamin K<sub>2</sub> supplementation for osteoporosis
- One meta-analysis of vitamin K<sub>2</sub> supplementation for hepatocellular cancer
- One systematic review of observational studies for coronary heart disease
- Five clinical trials of MK-7 for cardiovascular indications
- Three observational studies for mortality
- Three observational studies for cardiovascular indications
- One observational study for diabetes
- Two observational studies for cancer
- One case report for hypotension
- One preclinical study for diabetic neuropathy
- One review of preclinical studies in cancer

#### *Mortality – Vitamin K<sub>2</sub> epidemiology studies: **Mixed evidence***

In an observational study of 33,289 participants (ages 20-70) from the EPIC-NL cohort followed over 16.8 years, dietary intake of vitamin K<sub>2</sub> (highest quartile versus lowest quartile – Q4 vs Q1) was not associated with all-cause, cardiovascular (CVD), coronary heart disease (CHD), stroke, or cancer-related mortality ([Zwakenberg et al, 2016](#)). Similar results were reported in another observational study of 7,216 participants with a high cardiovascular disease risk in the PREDIMED cohort followed over 4.8 years. Those in the highest quartile of vitamin K<sub>2</sub> intake had no change in risk for CVD, cancer, or all-cause mortality compared to those in the lowest quartile. However, individuals who increased their consumption of vitamin K<sub>2</sub> over the follow-up period had a reduced risk of cancer mortality (**HR = 0.41; 95%CI 0.26-0.64**) and all-cause mortality (**HR = 0.55; 95%CI 0.42-0.73**) (no effect on CVD mortality) ([Juanola-Falgarona et al, 2014](#)). In another observational study of 24,340 participants from the EPIC-Heidelberg cohort followed for more than 10 years (ages 35-64 years) greater consumption of vitamin K<sub>2</sub> (Q4 vs Q1) reduced cancer mortality risk (**HR = 0.72; 95%CI 0.53-0.98** – results were also significant for the other quartiles) ([Nimptsch et al, 2010](#)).

#### *Coronary Heart Disease – Vitamin K<sub>2</sub> epidemiology studies: **Potential Benefit***

In a systematic review of two observational cohort studies, increased dietary intake of vitamin K<sub>2</sub> was associated with a reduced risk of CHD (**HR 0.59; 95%CI 0.40-0.86** for >32.7µg/day vs <21.6µg/day; and **HR = 0.91; 95%CI 0.85-1.00** per 10µg increase in consumption) ([Rees et al, 2010](#)). The authors suggest that the primary benefit comes from vitamin K<sub>2</sub> subtypes MK-7, MK-8, and MK-9 ([Gast et al, 2009](#)). In another cohort study of 2,987 Norwegian individuals followed over 11 years (ages 46-49), increased vitamin K<sub>2</sub> consumption (Q4 vs. Q1) was associated with a reduced risk of new-onset CHD (**HR = 0.52; 95%CI 0.29-0.94**). However, the results were no longer significant after controlling for calcium and saturated fatty acid intake ([Haugsgjerd et al, 2020](#)).

#### *Coronary Calcification – Vitamin K<sub>2</sub> epidemiology studies: **Potential benefit***

In a cross-sectional study of 564 post-menopausal women, high consumption of vitamin K<sub>2</sub> (Q4 vs. Q1) was associated with a lower risk of coronary calcification (**prevalence rate = 0.80; 95%CI 0.65-0.98**) ([Beulens et al, 2009](#)). In a cross-sectional study of 103 patients (avg age 64), plasma levels of MK-4 and MK-7 were not associated with coronary artery calcification (CAC) score ([Torii et al, 2016](#)).

#### *Cardiovascular disease – MK-7 Clinical Trials: **Mixed evidence***

80 community dwelling individuals under the age of 70 with a history of hypertension, diabetes, or previously diagnosed vascular disease were treated with 100µg/day of MK-7 (MenaQ7, NattoPharma) or placebo for six months. Levels of desphospho-uncarboxylated Matrix Gla Protein (dp-ucMGP – a protein

that plays a role in vascular calcification) decreased in the treated group. There were no significant differences in any cardiovascular outcome (endothelial function, carotid-radial pulse wave velocity, augmentation index, blood pressure, carotid intima-media thickness, cholesterol) ([Fulton et al, 2015](#)).

244 postmenopausal women (avg age 60) were treated with 180µg/day of MK-7 (MenaQ7, Nattopharma) for three years. MK-7 reduced local arterial stiffness in patients with high arterial stiffness at baseline (**p=0.018**). There were no changes in carotid intima-media thickness and a non-significant trend in a reduction in carotid-femoral pulse-wave velocity. Treatment reduced dp-ucMGP ~50% but had no effect on other circulating biomarkers (fasting glucose, hsCRP, IL-6, TNF-α, VCAM, E-selectin, advanced glycation end products) ([Knapen et al, 2015](#)).

In a study of 60 individuals (40-65 years of age) treated with 180 or 360µg/day of MK-7 (MenaQ7, Nattopharma) over 12 weeks, there was a reduction in dp-ucMGP in the treatment groups (31% and 46%, respectively), though there was no change in other plasma biomarkers (glucose, HOMA-IR, LDL-c, HDL-c, triglycerides, blood pressure) ([Dalmeijer et al, 2012](#)).

#### *Vascular Calcification – MK-7 Clinical Trials: **No Benefit/Detrimental***

In a study of 68 participants with type 2 diabetes randomized to either 360µg/day of MK-7 (MenaQ7, Nattopharma) or placebo, treatment over six months had no effect on vascular calcification. However, there was an increase in a measure of active calcification (<sup>18</sup>F-NaF PET target-to-background ration) (**p=0.03**) which was especially prominent in patients with no baseline vascular calcification. However, there was a high dropout rate in the placebo group, higher vascular calcification in the treatment group, and many of the patients took vitamin K<sub>2</sub> at baseline ([Zwakenberg et al, 2019](#)).

#### *Hypotension – Case Report: **N/A***

There is one case report of a 62-year-old man who developed mild hypotension (100/50 mm Hg) after three days of taking 100µg/day of vitamin K<sub>2</sub> (Solgar). He developed hypotension again after rechallenged with vitamin K<sub>2</sub>. The author speculates it could be due to a drug interaction with alfuzosin, an alpha blocker used to treat benign prostatic hyperplasia and hypertension ([Eleftherios Teperikids, 2012](#)).

#### *Exercise – MK-7 Clinical Trials: **Potential Benefit***

26 aerobically trained athletes were treated with MK-7 (MyoMax, Nu Science Trading – 300µg/day for four weeks and 150µg/day for four weeks) or placebo over eight weeks. MK-7 increased cardiac output by 12% (**p=0.031**) ([McFarlin et al, 2017](#)).

*Diabetes – Vitamin K<sub>2</sub> epidemiology studies: Potential Benefit*

In a cross sectional and longitudinal study of 625 participants, high vitamin K<sub>2</sub> intake (highest tertile vs lowest tertile) was associated with a reduced prevalence of metabolic syndrome (**prevalence rate = 0.72, 95%CI 0.52-0.99**). In the longitudinal cohort, high intake of vitamin K<sub>2</sub> was also associated with a lower prevalence of metabolic syndrome (**prevalence rate = 0.62; 95%CI 0.40-0.95**) ([Dam et al, 2015](#)).

*Diabetic Neuropathy – Vitamin K<sub>2</sub> preclinical study: N/A*

One preclinical study suggested that vitamin K<sub>2</sub> improved the nociceptive threshold of both diabetic and non-diabetic mice, with no differences in improvements between the two ([Onodera et al, 2001](#)).

*Cancer – Vitamin K<sub>2</sub> epidemiology studies: No Benefit*

Preclinical studies suggest that vitamin K<sub>2</sub> has anti-cancer activity in several cell cancer lines ([Hoyt et al, 2019](#)). In an observational study from the EPIC-Heidelberg cohort with 24,340 participants followed for greater than 10 years (ages 35-64 years) cancer incidence was not different in participants who consumed greater vitamin K<sub>2</sub> (Q4 vs Q1) ([Nimptsch et al, 2010](#)). In an observational study with 28,356 patients followed over 11.8 years (avg age ~62), high intake of vitamin K<sub>2</sub> was not associated with a reduced prostate cancer risk ([Hoyt et al, 2019](#)).

*Cancer – Vitamin K<sub>2</sub> Supplementation: Potential Benefit*

In a meta-analysis of five randomized controlled trials, supplementation of vitamin K<sub>2</sub> for the recurrence of hepatocellular cancer after hepatic resection or local ablative therapy was not associated with a reduced risk of cancer recurrence after 1 year but was associated with a reduced risk of cancer recurrence at 2 years (**RR = 0.66; 95%CI 0.47-0.91**) and 3 years (**RR = 0.71; 95%CI 0.58-0.85**). However, the authors note there is insufficient data on the long-term survival of vitamin K<sub>2</sub> supplementation ([Riaz et al, 2012](#)).

*Osteoporosis – Vitamin K<sub>2</sub> clinical trials: Potential Benefit*

In a meta-analysis of 18 RCTs in patients with osteoporosis, vitamin K<sub>2</sub> was associated with increased lumbar bone mineral density (BMD) (five studies, **mean difference (MD) = 0.05g/cm<sup>2</sup>; 95%CI 0.01-0.09g/cm<sup>2</sup>**) with a non-significant effect on fractures (five studies) when compared with placebo. When compared with other anti-osteoporotic drugs, there were no significant differences with the use of vitamin K<sub>2</sub> ([Su et al, 2019](#)).

**Safety:** Vitamin K<sub>2</sub>, in doses used in clinical trials, may be relatively safe for long-term use.

Types of evidence:

- One meta-analysis of clinical trials for osteoporosis
- A review from the European Food Safety Authority
- WebMD.com link

In a meta-analysis in patients with osteoporosis, vitamin K<sub>2</sub> was associated with an increased risk of adverse events (two studies, RR = 1.47; 95%CI 1.07-2.02) and adverse drug reactions (four studies, RR = 1.29; 95%CI 1.07-1.56) (note, many of the studies in these trials used vitamin K<sub>2</sub> in combination with another drug). There were no significant differences in the incidence of serious adverse events ([Su et al, 2019](#)).

The European Food Safety Authority conducted a review of clinical trials with MK-7 and concluded there were no adverse events on blood coagulation at doses up to 60µg/day for MK-7. In clinical trials of 180µg/day up to three years or 1080µg three times weekly for 8 weeks there were no significant adverse effects other than gastrointestinal issues due to the product's smell ([Marles et al, 2017](#)).

[WebMD.com](#) says that vitamin K<sub>2</sub> is likely safe for most people, with potential gastrointestinal side effects.

**Drug interactions:** Vitamin K<sub>2</sub> should not be used with vitamin K antagonists, such as warfarin, some anti-coagulants such as anisindione, dicumarol, and some cholesterol drugs, such as cholestyramine, colesevelam, and colestipol. Find a full list at [drugs.com](#).

**Sources and dosing:** Check the label when buying vitamin K<sub>2</sub>. Many supplements labeled vitamin K<sub>2</sub> actually contain MK-4 while MK-7 is thought to be the most important for age-related diseases (although MK-4 is most prevalent in the brain, there is little evidence that supplementation is beneficial for brain health). In addition, look for fermented forms of MK-7. The most commonly used form is [MenaQ7](#). Doses have been used between 100µg/day to 360µg/day.

**Research underway:** Using search terms vitamin K<sub>2</sub> and menaquinone, 16 clinical trials were found on [clinicaltrials.gov](#). Most of the trials were for vascular calcification, metabolic syndrome, or osteoporosis.

**Search terms:**

- menaquinone-4 + Alzheimer, cardiovascular, mortality, diabetes, cognition, neuropathy, hypotension, cancer, lifespan, apoe4, senomorphic
- vitamin K2 + alzheimer, cardiovascular, mortality, diabetes, cancer, cognition, neuopathy, hypotension, lifespan, apoe4, senomorphic
- menaquinone-7 + alzheimer, cardiovascular, diabetes, hypotension, neuropathy, cognition, lifespan, hypotension, cancer, apoe4, senomorphic
